

Dr Lowe's Patient Instructions for Botulinum Toxin (Xeomin® or Botox®)

- 1. Botulinum Toxin injections are usually given every 3-6 months.
- 2. It is best to avoid blood thinners such as NSAIDS (Advil, Aleve, Ibuprofen, etc.) for two days prior to treatment, and Aspirin containing products 7 days prior to application to decrease the risk post application bruising. Patients are required to obtain approval from their prescribing physician whenever discontinuing recommended blood thinners.
- 3. It is important for you to write down the week following injections the areas with the best and worse responses
- 4. The dose can be altered and applied differently based on your particular response
- 5. Botulinum Toxin is not without risks. It is a toxin that inhibits muscle movement temporarily. It can travel after application to unintended areas causing paralysis of the eyelid, face, and lip.
- 6. Patients can have allergic reactions to Botulinum Toxin or even become resistant to the medication with time.
- 7. Botulinum toxin injections can result in local reaction, redness, numbness and bruising. The injections are often applied close to nerves which may be injured during application
- 8. Please inform the physician if any unexpected reactions occur after an injection
- 9. Botulinum is not a permanent solution for wrinkles, but more lasting surgical treatments are available that can achieve similar results.
- 10. Active movement of the muscles in the treated areas after application will distribute the Botulinum Toxin more evenly.
- 11. The maximum response can be expected within 5-7 days after injection
- 12. Do not receive Botulinum Toxin before any major events, due to possible bruising and redness.
